How do LCDs (liquid crystal displays) work?

Flat panel displays are thin panels of glass or plastic used for electronically displaying text, images, or video. LCD, OLED and MicroLED displays are not quite the same, since LCD uses a liquid crystal that reacts to an electric current blocking light or allowing it to pass through the panel, whereas OLED/microLED displays consists of electroluminescent organic materials /inorganic that generate light when a current is passed through the material. LCD, OLED/MicroLED displays are driven using LT

Liquid crystal display (LCD), electronic display device that operates by applying a varying electric voltage to a layer of liquid crystal, thereby inducing changes in its optical properties. LCDs are commonly used for portable electronic games, as viewfinders for digital cameras and camcorders, in video projection systems, for electronic billboards, as monitors for computers, and in flat-panel televisions.

Liquid crystal display | electronics | Britannica

Flat-panel displays can be divided into two display device categories: volatile and static. Volatile displays require that pixels be periodically electronically refreshed to retain their state (e.g. liquid-crystal displays (LCD)). A volatile display only shows an image when it has battery or AC mains power.
